Born in the Kalinin region in 1907 and a graduate of Moscow State University, Prof. Striganov is presently head of the Atomic Spectroscopy Laboratory of the I. V. Kurchatov Institute of Atomic Energy and a member of the Committee on Spectroscopy of the Academy of Sciences of the USSR. His published work deals with the development of methods of atomic emission spectrum analysis, the study of optical spectra, the hyperfine structure of the spectra of heavy elements, and development of the spectroscopic diagnosis of plasmas.

The original Russian text was published by Atomizdat in Moscow in 1966 and has been corrected and updated by the authors for this edition. In order to make this volume as useful and convenient as possible, last-minute additions and corrections have been incorporated into the tables in their proper locations at the expense of such typographic niceties as page length and spacing. This procedure also accounts for the lettered—occasionally only partly filled—pages interpolated at various points.

FOREWORD

Tables of Spectral Lines of Neutral and Ionized Atoms was first published in Moscow in 1966. All misprints and errors that have come to our attention have been corrected, and additions based on journal articles have been made for the Plenum Press edition. In particular, additions have been made in the tables for Li [4], C I [1], N I [1], N IV [12], and N V [14].

Such highly important spectra as those of N IV, N V, O IV, O V, and O VI in the visible and partially in the ultraviolet regions have, until recently, received almost no attention in the laboratory. The tables of these spectra include astrophysical data from B. Edlen (Z. Astrophys., 7:378, 1933) and C. E. Moore (A Multiplet Table of Astrophysical Interest, Part I, N.B.S., 1945) with rather rough estimates of the wavelengths of the spectral lines. But as the spectra of highly ionized atoms have been studied in the laboratory, these values have been determined more precisely, and we have striven to incorporate them in the American edition of the book. For the spectra of N IV and N V, we have employed the recent, comprehensive papers of R. Hallin (Arkiv for Fysik, 32:201, 1966; 31:511, 1966), in which the system of energy levels was refined and expanded, and many classified lines in the visible, ordinary ultraviolet, and vacuum ultraviolet regions are cited. In addition, our tables retain certain lines in the spectra of N IV, N V, O IV, and O V from the above-mentioned papers of Edlen and Moore, for which we calculated wavelengths according to the energy levels of Hallin. These lines are easily detected, since there are no intensity estimates in the second column of the tables.

We shall be very happy if the data in this book on the spectra of 22 elements are of use to physicists and engineers.

PREFACE

Optical atomic spectroscopy finds ever-widening application in various fields of physics and technology. Spectroscopic methods have acquired great importance for the determination of the most important parameters of plasma in discharge tubes, in plasma apparatus, and in ion sources. The development of quantum generators is closely linked with the utilization of the results of optical spectroscopy, and it is therefore very important for investigators to have detailed data on the spectra of atoms and their ions. However, to date no books have been published, either here or abroad, containing sufficiently complete tabulations of the spectra of neutral and ionized atoms in all regions of the optical spectrum, and it has therefore been necessary to refer to individual journal articles, which has made work on the interpretation of spectra difficult.

Harrison's tables of spectral lines, although fairly complete, only cover the spectra of neutral and singly ionized atoms. The tables of A. N. Zaidel, V. K. Prokof'ev, S. M. Raiskii, and E. Ya. Shreider are mainly designed for spectral analysis, and only isolated very intense lines are given in the spectra of higher degrees of ionization. In Charlotte Moore's tables of multiplets the classification of the most intense lines of almost all the elements for many degrees of ionization is given, but these tables are not complete enough, and their arrangement according to multiplets makes work on the analysis of spectra difficult. Very complete tables on the far-UV region of the spectrum have recently been published by Kelly, but the classification of the lines is not given.

This book contains the emission spectra of 22 of the elements with which we most frequently have to deal in the investigations of plasmas in all their forms and modifications. For each spectral line the wavelength, intensity, and classification are given. The book contains the spectra of all the gaseous elements except radon, of all the alkali metals except rubidium, which is rarely met in nature, and the radioactive francium, and of carbon, magnesium, aluminum, silicon, calcium, titanium, iron, and copper, which sometimes are present in plasma as impurities. The choice of elements is to some extent arbitrary, and it might have been possible to include a few more if space had permitted.

For each element, in addition to the spectrum of the neutral atom, the spectra of several of its ions are given. In all, the tables contain over 30,000 lines in the IR, visible, near-UV and far-UV regions of the spectrum. In the compilation of the tables there is no demarcation of the region of the optical spectrum at either end.

These tables surpass all previously published tables in completeness for most of the elements (the exceptions are the spectra of Ca I and II, Ti I and II, and Fe I and II), and in particular the spectra of the gases have been greatly extended. Moreover, we give all necessary characteristics of the lines — their classification. In the examination of original papers we have come across many inaccuracies and errors in the classification of lines, and all the errors detected have been corrected.

In compilation of the tables for certain elements assistance was given by A. I. Odintsov, G. A. Odintsova, Z. I. Shlepkova, P. P. Gavrin, Yu. P. Dontsov, V. V. Eliseev, L. N. Kaporskii, and V. P. Kachalov. The general editing and checking of all the tables were done by Prof. A. R. Striganov.

**TABLES OF SPECTRAL LINES OF
NEUTRAL AND IONIZED ATOMS**

INTRODUCTION

The book consists of four main sections, in which spectral lines are assembled in the order of diminishing wavelength. In the first section the most intense lines are given for each element, and these are arranged according to the degrees of ionization of the atoms. The first column contains the wavelength in angstroms, the second the intensity of the line, and the third the energy of the upper level in electron-volts. The second section gives a summary table of the most intense lines arranged according to wavelength. Here the first column contains the wavelength in angstroms, the second the element to which it belongs and its degree of ionization, and the third the intensity of the line. The tables of the most intense lines in the first and second sections of the book are intended to facilitate rapid orientation to the spectrum under investigation and the detection of the main components and impurities in the plasma.

The third section gives complete tables of the spectral lines and their classification. As in the first section, the lines of elements are arranged in order of increasing atomic number, and in the table for each particular element, in order of increasing degree of ionization. In these tables the first column lists the wavelength in angstroms according to the most reliable literature sources, the second the intensity according to the same source, and the third and fourth the energies of the lower and upper levels in electron-volts. The relation $1 \text{ eV} = 8066.1 \text{ cm}^{-1}$ was used for conversion from cm^{-1} to eV. The fifth column lists the transition expressed by the usual spectroscopic symbols for the lower and upper levels. The sixth column gives the corresponding internal quantum numbers of the total angular momentum of the electron. The tables of this section contain not only classified lines, but also lines which have been shown to belong to the given degree of ionization of the atom but whose classification has not yet been established. For some elements there are fairly intense lines which cannot yet be definitely assigned to the neutral atom or one or another ion. Such lines are collected in supplementary tables of unidentified lines.

The accuracies with which wavelengths have been measured by different authors are different. Lines are found in the tables for which the wavelength stated has a possible error of more than 1 \AA . For some elements lines are given whose wavelengths were measured accurately to the fourth decimal place by the interferometric method. Such lines can be used as secondary standards for the accurate measurement of wavelengths of lines in the spectra under

investigation. All wavelengths of more than 2000 \AA were measured in air; shorter wavelengths are the values in a vacuum.

Intensities of lines are taken directly from the original papers, so that in the spectra of different atoms, and also in different regions of the spectrum of a given atom, different intensity scales are met. In most of the spectra the 10-grade intensity scale is used with some extension beyond 10 for very bright lines and with the use of the symbols 0 and 00 for very weak lines. This scale is used in almost all the spectra in the far-UV region, and also in the spectra of highly ionized atoms. For neutral and singly ionized atoms a 1000-grade scale is used most frequently with some extension for bright lines. In a number of spectra the 100-grade scale is used. Only in a few cases, when different authors used different scales for the estimation of the intensities of the lines which they measured, the intensities of a small part of the lines have been adjusted to a common scale. This was done in the spectra of Ne I, Ar I, Kr I, and Xe I, as a result of which the intensities of lines in the IR, visible, and near-UV regions are all expressed on the 1000-grade scale. In the IR and visible regions of the spectrum of He I [2] we used a 10,000-grade scale. For convenience of comparison with lines in the UV region these intensities are halved. In the spectrum of F I [1] a scale is used which reaches 500,000 units for the very brightest lines. In this case, in all regions of the spectrum except the far-UV the intensities of the lines are diminished tenfold.

From this it will be seen that the comparison of the intensities of lines in different regions of the spectrum, and especially of spectra of different degrees of ionization and of different elements, must be approached with great caution. This is not entirely because some authors use different scales and often estimate intensities visually without allowing for the spectral sensitivity of the photographic plate. It is necessary to remember also that the relative intensities of lines depend greatly on the source in which the spectrum is excited and on its parameters. Lines of different degrees of ionization are particularly sensitive in this respect. It was not possible to describe the source and conditions of excitement for each of the spectra presented in this book. It may be stated, however, that for metals and carbon the spectra of neutral atoms were excited with the aid of an electric arc or a discharge tube with a hollow cathode, while the spectra of ionized atoms were obtained with a condensed spark. In the case of gases the spectra of neutral and singly ionized atoms were excited in a Geissler tube. The spectra of higher degrees of ionization were obtained with the aid of a powerful spark in a vacuum. More detailed information on this question will be found in the literature, which is given in the book for each element.

The classification of the lines is derived from the original papers and also from Moore's tables [5, 6]. All old notations of levels have been replaced by modern ones in accordance with Moore's book "Atomic Energy Levels," since the publication of which many new levels have been established and the classification of a number of spectra has been greatly extended (C I, C II, N II, O I, F I, Na I, Mg I, Mg II, AC I, Si I, Si II, Si III, Si N, Cl I, Ar II, K I, Ca III). All this has been taken into account in the present book.

In the spectral tables in Section III for H, He, Li, C, N, O, Ne, Na, Ar, K, Kr, Xe, and Cs all classified spectral lines are included, but weak unclassified

lines with intensities of $I = 1, 0$, or 00 on the 10-grade scale for which the transitions are unknown and for which it is unknown whether the spectrum belongs to the neutral atom or an ion are excluded. In the case of the spectrum of Ar II [11, 12], in view of its very large size classified lines with intensities I of 0.5 and 0 are also excluded. In the spectra of high degrees of ionization there is no abridgment. In Table 1 we give the numbers of lines in Section III for each of the elements listed and in some cases the number of unidentified lines which have not yet been assigned to the neutral atom or an ion. The table also gives the total number of lines for each element.

From the spectra of neutral and singly ionized atoms of F, Mg, Al, Si, Cl, Ca, Ti, and Cu weak classified lines with $I = 1$ or 0 on the 10-grade scale and unclassified lines with $I = 2, 1$, or 0 are excluded. From the spectrum of Ti I classified lines with $I = 2$ and unclassified lines with $I = 4$ or 3 are also excluded. From the spectra of Fe I, II, and III all lines with $I = 4, 3, 2, 1$, or 0 are excluded. Information on the numbers of lines given for these elements in this book is given in Table 2.

The fourth section of the book consists of a summary table of all lines arranged according to wavelength. For each line it is stated whether it belongs to the neutral atom or an ion, and its intensity is given.

The fifth section lists forbidden lines belonging to quadrupole and magnetic dipole transitions. Many of these lines are observed under ordinary conditions, and some are found in the spectra of the sun and the stars. In the same section the edges of the bands of the more important molecules are given, and there is a table of the wavelengths of lines in the molecular spectrum of hydrogen H₂.

Below, for each element we list the literature used in the compilation of the data of the tables.
